ABSTRACT

Purpose of this study to determine the coronary risk scores in adult male and female of control and treatment groups. The study comprised a sample of people (29-91 years, n=547) and the entire elderly population (33-84 years, n=444). The risk score will be analysed based on sex, age, smoking, diabetes s, systolic blood pressure, total cholesterol, and HDL. The risk profile based on age and sex one group will be compared with the other group so find the risk score difference between Group. Based on these results, in the groups studied, the risk of coronary artery disease risk score may be not differing between the control and treatment group whoever differs when compared based on Gender and Age and Smoking History

Key words: coronary artery disease, risk score, population-based study

Introduction

Background:

Cardiovascular diseases account for 18 million deaths per year in the world, coronary artery diseases and cerebrovascular diseases being responsible for two thirds of these deaths and for approximately 22% of the 55 million deaths due to all causes. Estimates on mortality due to cardiovascular diseases according to the region indicate that developing countries contribute with a greater part of the overall burden of mortality due to the disease than developed countries, with a relative excess of 70%.

Despite this evidence, epidemiological studies have shown that cardiovascular diseases are a relatively rare cause of death in the absence of major risk factors Almost 75% of the new cases of cardiovascular diseases occurring in developed countries in the 1970s and 1980s could be explained by inadequate diet and physical activity, expressed by high lipid levels, obesity, and increased blood pressure, associated with smoking. The study of these risk factors relates their presence and intensity to the development of the disease. These prospective studies were responsible for the development of risk scores, which allow for the estimation of the probability of developing a certain cardiovascular disease in a defined time

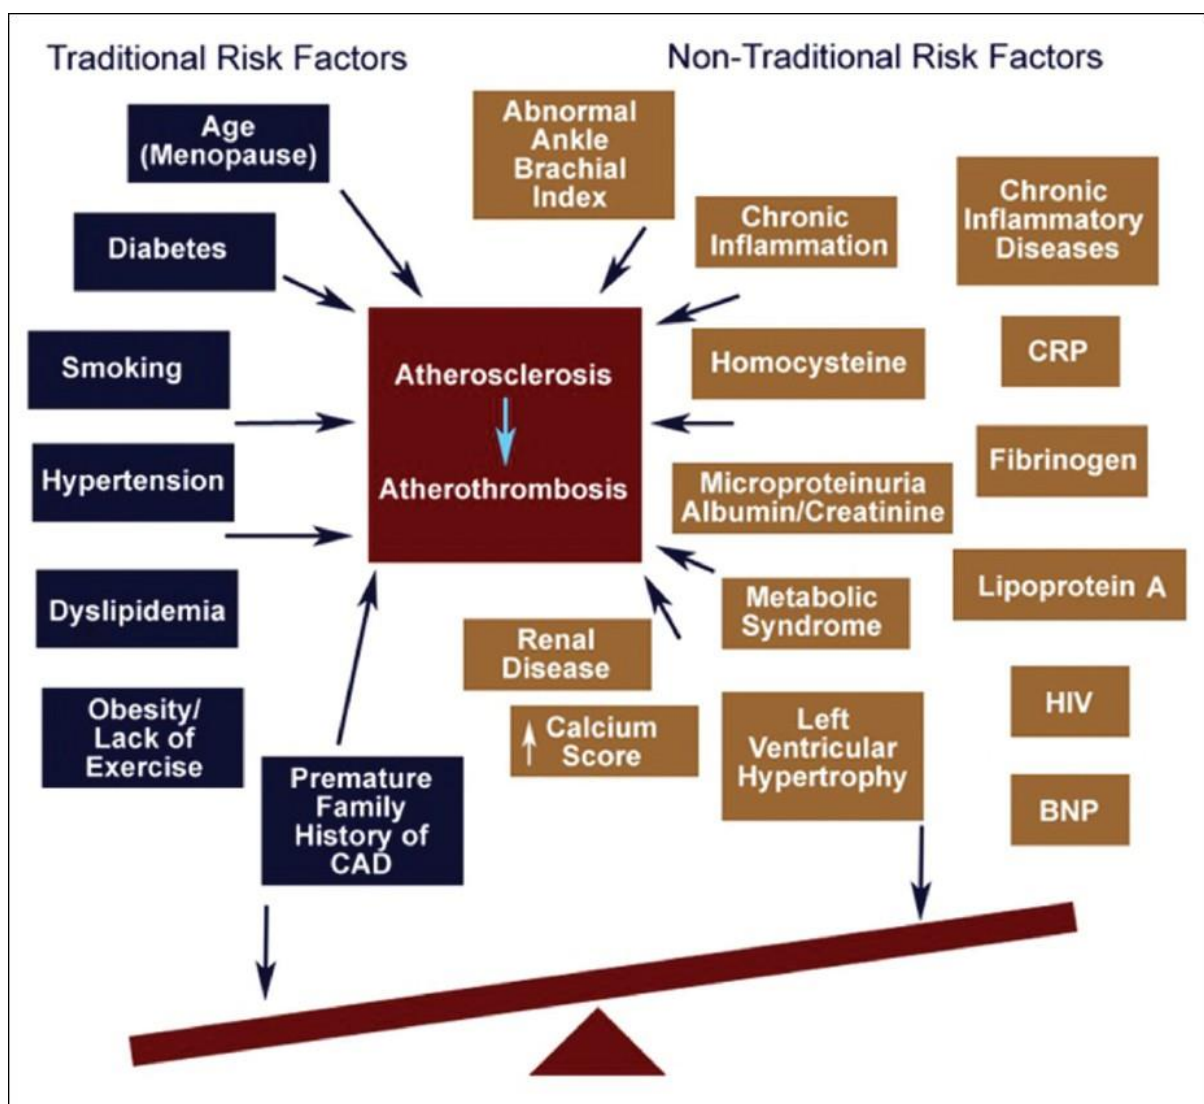

interval. These risk scores, in addition to being useful in foretelling a cardiovascular event, aid in its prevention and in the reduction in its incidence in individuals and populations.

The present study aimed at disclosing the risk profile of coronary artery disease between two groups which are control and treatment by estimating the risk of developing of coronary heart disease using statistical Analysis major factor which cause the death

The major risk factors:

The factor risk factor which contribute most are categorized in two ways.

1. Traditional
2. Non-Traditional

In this study we have selected following traditional method.

Age.

SysBp

Cholesterol

HDL

Diabetes

Smoking

Hypertension

Previous History

Data Source

For this study two group (Control and Treatment) of male and female taken. For these group we have the recorded data which will used to perform the analysis to investigate the risk score difference between control and treatment groups. We have a sample a size of 547 in control group which has male and female both between the age group of 29 to 91 and a sample size of 444 in treatment which also has male and female both between an age group of 33 to 84. From entire dataset we have selected the Traditional Factors (mentioned above) column to perform the statistical Analysis to build the risk difference between the Control and Treatment Group. Data has been manipulated using the R language and Categorical data like hypertension, diabetes and Previous.MI which has missing value, has been removed where in for continuous data like HDL, Cholesterol, Systolic BP has been replaced with mean value of that data. While Data manipulation and filtering outlier's presence was noticed in dataset however removing the outliers was resulting to very less sample size which is not good for Analysis as result will not that accurate if the sample would be small.

Methods

Statistical analysis was performed using Minitab statistical software, a significant difference between the groups is determined by analysis of variance (ANOVA) using smoking Status, and 2 sample t and paired t was used for assessment of mean difference between and within the groups. Statistically significant differences are marked with probability $p < 0.05$.

Comparison of the groups was performed on the basis age with a logistic linear regression analysis and the results were described as odds ratios with 95% confidence intervals (95% CIs).

The size of the samples of Control and Treatment group is sufficient to estimate the prevalence of risk factors to 5% significance level, with a confidence interval of 95%.

The parameters used for constructing the risk score were as follows: sex, age, smoking, diabetes, systolic blood pressure, cholesterol, and HDL.

As per the medical research conducted in past cholesterol and Sysbp are directly proportional to increase of risk getting a CHD (Coronary Heart Risk) wherein HDL is protective factor, so an average risk score is calculated for both group which is used a baseline character for Primary analysis.

$$\text{AvgScore} = \text{Cholesterol} + \text{Sysbp} - \text{HDL}$$

Statistical Analysis:

For this study, we have divided the analysis in two categories considering our primary and secondary baseline endpoints.

1. Primary Endpoint Analysis

2. Secondary Endpoint Analysis

Primary Endpoint Analysis

1: Gender

First primary analysis is done on AvgScore calculated using the Cholesterol, Sysbp and HDL within Control and Treatment Group taking gender in account.

Firstly, we performed the subjective analysis using the scatterplots and box plots of control and treatment group males and females which was preceded with formal paired t test for both groups

Figure 1: Boxplots of Control and Treatment group based on gender comparing the mean difference.

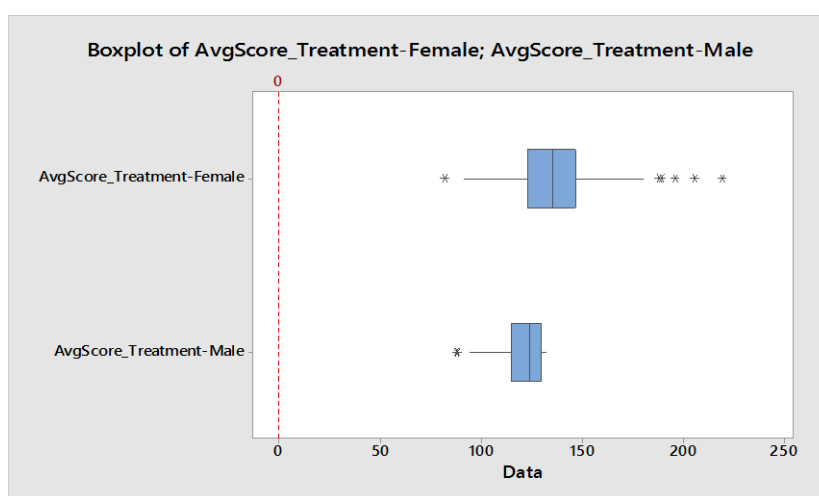

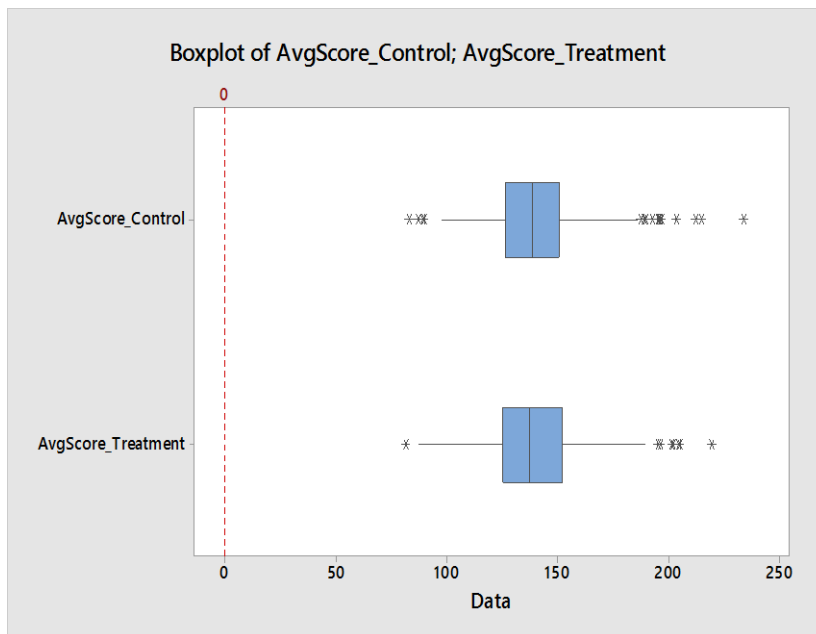

Table:

| Descriptive Statistics: AvgScore_Control-Female; ... core_Control-Male | | | | | | | | | |
|--|---------|-----|--------|---------|-------|---------|--------|--------|--------|
| Statistics | | | | | | | | | |
| Variable | N | N * | Mean | SE Mean | StDev | Minimum | Q1 | Median | Q3 |
| AvgScore_Control-Female | 132 | 0 | 139.03 | 1.93 | 22.14 | 89.23 | 124.38 | 137.85 | 148.00 |
| AvgScore_Control-Male | 132 | 0 | 123.60 | 0.946 | 10.87 | 82.73 | 117.86 | 125.31 | 131.79 |
| Variable | Maximum | | | | | | | | |
| AvgScore_Control-Female | 233.83 | | | | | | | | |
| AvgScore_Control-Male | 137.81 | | | | | | | | |

Figures of boxplot shows that the boxplots overlap for both Control and Treatment groups which shows the signs of difference and the outliers are there with the possibility to make a diligent about the reliability of this value. Confirming the general idea that in the control group there is a difference between Early and After pregnancy because the boxplot far way for the zero. To confirm this, we must go for formal Pair t test within Control and Treatment group

Table 1: Paired t test of control male and female and Treatment male and female.

| Estimation for Paired Difference | | | | Estimation for Paired Difference | | | |
|---|-------|---------|--------------------------------------|---|-------|---------|--------------------------------------|
| Mean | StDev | SE Mean | 95% CI for $\mu_{\text{difference}}$ | Mean | StDev | SE Mean | 95% CI for $\mu_{\text{difference}}$ |
| 15.43 | 13.94 | 1.21 | (13.03; 17.83) | 16.28 | 14.97 | 1.32 | (13.67; 18.90) |
| $\mu_{\text{difference}}$: mean of (AvgScore_Control-Female - AvgScore_Control-Male) | | | | $\mu_{\text{difference}}$: mean of (AvgScore_Treatment-Female - AvgScore_Treatment-Male) | | | |
| Test | | | | | | | |

| | | | |
|------------------------|---------------------------------------|------------------------|---------------------------------------|
| Null hypothesis | $H_0: \mu_{\text{difference}} = 0$ | Test | |
| Alternative hypothesis | $H_1: \mu_{\text{difference}} \neq 0$ | Null hypothesis | $H_0: \mu_{\text{difference}} = 0$ |
| T-Value | P-Value | Alternative hypothesis | $H_1: \mu_{\text{difference}} \neq 0$ |
| 12.72 | 0.000 | T-Value | P-Value |
| | | 12.31 | 0.000 |

Our p value for control and treatment groups is .001 which is more less .05 which indicates strong evidence against the null hypothesis, so we reject the null hypothesis. That shows, Female of control and Treatment group has less change of getting the CHD. To investigate the difference of risk profile difference between the control and treatment

Group we chose for the subjective analysis.

Figure 2: Scatter plot of control and treatment group comparing the AvgScore.

Figure shows that there is positive relation between control and treatment group which shows the evidence of no difference in risk profile between control and treatment. To make sure that our assumption is true we have carry out the formal analysis (2 sample t test).

Table 2:

Two-Sample T-Test and CI: Control and Treatment

AvgScore

μ_1 : mean of AvgScore when Arm = Control

μ_2 : mean of AvgScore when Arm = Treatment

Difference: $\mu_1 - \mu_2$

Equal variances are not assumed for this analysis.

Descriptive Statistics: AvgScore

| Arm | N | Mean | StDev | SE Mean |
|-----------|-----|-------|-------|---------|
| Control | 429 | 140.2 | 21.0 | 1.0 |
| Treatment | 429 | 139.4 | 22.2 | 1.1 |

Estimation for Difference

| | |
|-------------|---------------|
| 95% CI for | |
| Differences | Difference |
| 0.89 | (-2.01; 3.79) |

Test

| | | |
|------------------------|-----------------------------|---------|
| Null hypothesis | $H_0: \mu_1 - \mu_2 = 0$ | |
| Alternative hypothesis | $H_1: \mu_1 - \mu_2 \neq 0$ | |
| T-Value | DF | P-Value |
| 0.60 | 853 | 0.549 |

Formal analysis shows that our 95% CI contain zero however the mean difference is positive which shows that risk profile between control and treatment does not differ. p-value (>0.05) indicates weak evidence against the null hypothesis, so you fail to reject the null hypothesis.

2: Age, Gender Vs AvgScore.

Like gender age is also which makes a remarkable difference while investigate the risk profile of CHD. Correlation coefficient shows the positive equation so linear regression analysis is performed to find where the response variable will the manual calculated AvgScore dependent on the Age and Gender.

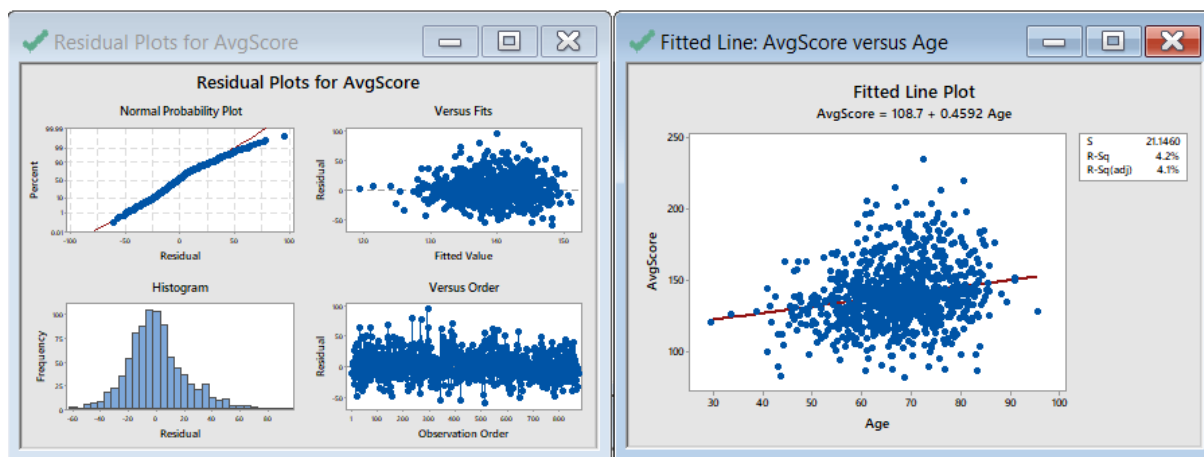

Table 3:

| Analysis of Variance | | | | | |
|----------------------|-----|--------|---------|---------|--------------|
| Source | DF | Adj SS | Adj MS | F-Value | P-Value |
| Regression | 2 | 18630 | 9315.2 | 20.90 | 0.000 |
| Age | 1 | 17908 | 17908.3 | 40.18 | 0.000 |
| Gender | 1 | 1739 | 1739.2 | 3.90 | 0.049 |
| Error | 867 | 386389 | 445.7 | | |
| Lack-of-Fit | 528 | 238328 | 451.4 | 1.03 | 0.372 |
| Pure Error | 339 | 148061 | 436.8 | | |
| Total | 869 | 405019 | | | |

Table 4:

| Coefficients | | | | | |
|--------------|---------------|---------|---------|--------------|------|
| Term | Coef | SE Coef | T-Value | P-Value | VIF |
| Constant | 105.37 | 5.35 | 19.69 | 0.000 | |
| Age | 0.4758 | 0.0751 | 6.34 | 0.000 | 1.01 |
| Gender | | | | | |
| Male | 3.11 | 1.57 | 1.98 | 0.049 | 1.01 |

Figure 3:

The histogram is roughly bell-shaped, so it is an indication that it is reasonable to assume that the residuals have a normal distribution. The pattern of the normal probability plot is straight, so this plot also provides evidence that it is reasonable to assume that the errors have a normal distribution.

In fits vs residual plot the variance is roughly the same all the way across and there are no worrisome patterns. There seems to be no difficulties with the model or data.

From order vs residual graph, it's clear that the order of the data doesn't give any information, so the sample is independent. There is no evidence of a bend in the fits vs residual plot, so we can assume that the model is linear.

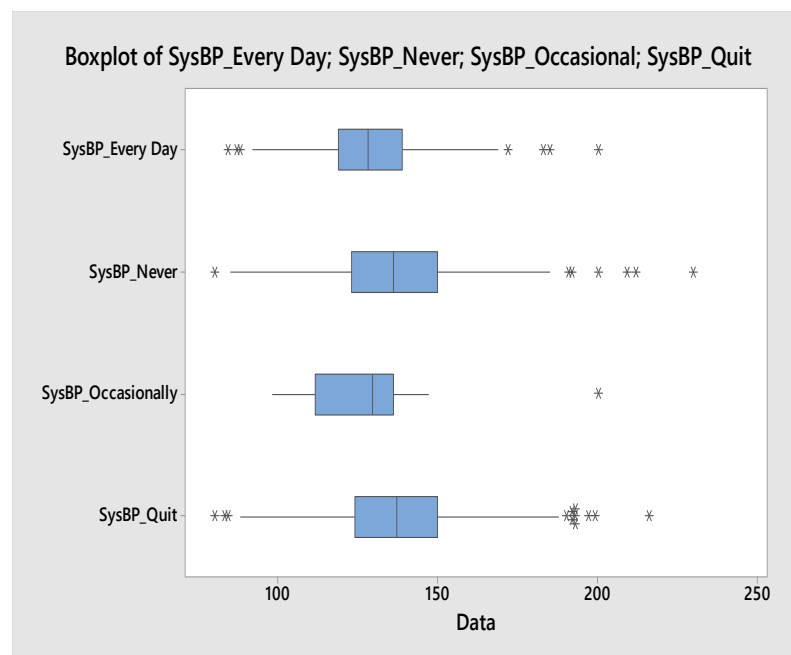

And the graphs show that there is positive relation between the AvgScore and age which indicates that as age increase the risk profile of CHD will be strong in higher age group and female are comparatively has less risk with male with increasing age. Coefficient value of Gender and Age versus AvgScore is positive which shows a strong positive impact and provide evidence the risk profile increase as the age increase, while categorising the gender risk profile is high in Men comparing to women which can be confirm with the p value that is almost equal to .05.

3: Smoking.Status and SysBp

Smoking.Status is directly proportional to Sysbp which is a major factor to create the risk profile among the population, so comparison is done of smoking status with Sysbp through boxplots following the One Way Anova and Tukey Comparison.

Figure 4: Box plot

Figure 5: Tukey Comparison

Descriptive Statistics: SysBP_Every Day; SysBP_Never; ... lly; SysBP_Quit

Statistics

| Variable | N | N * | Mea n | SE Mean | StD ev | Minim um | Q1 | Medi an | Q3 | Maxim um |
|-----------------|----|-----|----------|------------|-----------|-------------|--------|------------|--------|-------------|
| SysBP_Every Day | 10 | 0 | 131. | 2.00 | 20. | 84.00 | 119.00 | 128.00 | 139.00 | 200.00 |

| | | | | | | | | | | |
|--------------------|----|---|------|-------|-----|-------|------|-------|------|--------|
| SysBP_Never | 24 | 0 | 137. | 1.38 | 21. | 80.00 | 123. | 136.0 | 149. | 230.00 |
| | 4 | | 72 | | 55 | | 00 | 0 | 75 | |
| SysBP_Occasionally | 22 | 0 | 128. | 4.52 | 21. | 98.00 | 111. | 129.5 | 136. | 200.00 |
| | | | 09 | | 18 | | 50 | 0 | 00 | |
| SysBP_Quit | 48 | 0 | 137. | 0.975 | 21. | 80.00 | 124. | 137.0 | 150. | 216.00 |
| | 5 | | 79 | | 47 | | 00 | 0 | 00 | |

Boxplot for smoking status overlaps for all four group (Never, Quit, every day, Occasionally) and presence of outliers shows the weak proof for relying on this outcome however median line of all four pass through between the boxplots. But there is significant difference between the largest and smallest value of mean which supports to go for formal analysis.

Table 5:

One-way ANOVA: SysBP versus Smoking.Status

Method

Null hypothesis

All means are equal

Alternative hypothesis

Not all means are equal

Significance level

$\alpha = 0.05$

Equal variances were assumed for the analysis.

Factor Information

| Factor | Levels | Values |
|----------------|--------|--------------------------------------|
| Smoking.Status | 4 | Every Day; Never; Occasionally; Quit |

Analysis of Variance

| Source | DF | Adj SS | Adj MS | F-Value | P-Value |
|----------------|-----|--------|--------|---------|---------|
| Smoking.Status | 3 | 5736 | 1912.0 | 4.18 | 0.006 |
| Error | 854 | 390861 | 457.7 | | |

Total 857 396597

Model Summary

| S | R-sq | R-sq(adj) | R-sq(pred) |
|---------|-------|-----------|------------|
| 21.3935 | 1.45% | 1.10% | 0.53% |

Means

| Smoking.Status | N | Mean | StDev | 95% CI |
|----------------|-----|---------|--------|--------------------|
| Every Day | 107 | 131.17 | 20.72 | (127.11; 135.23) |
| Never | 244 | 137.72 | 21.55 | (135.04; 140.41) |
| Occasionally | 22 | 128.09 | 21.18 | (119.14; 137.04) |
| Quit | 485 | 137.789 | 21.472 | (135.882; 139.696) |

Pooled StDev = 21.3935

Tukey Pairwise Comparisons

Grouping Information Using the Tukey Method and 95% Confidence

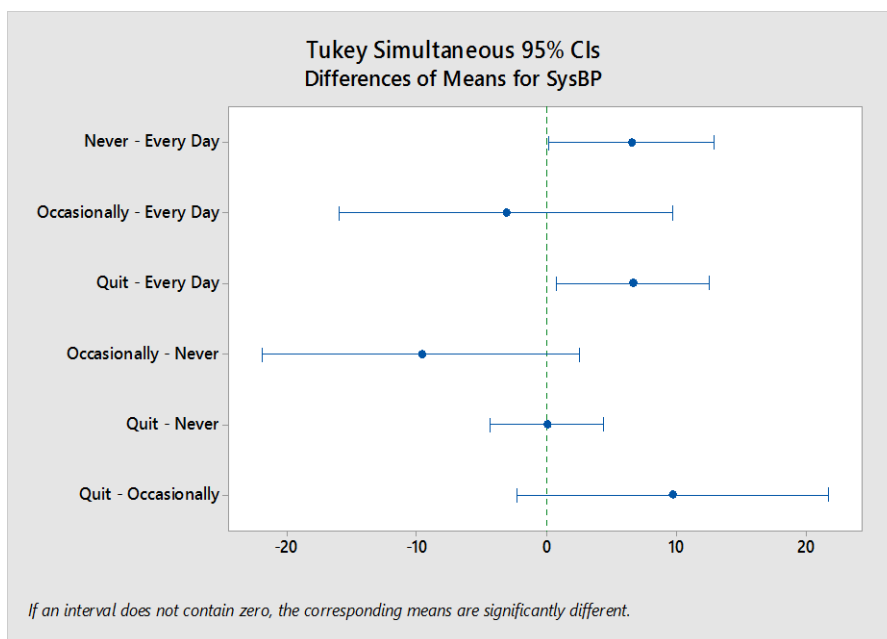

| Smoking.Status | N | Mean | Grouping | |
|----------------|-----|---------|----------|---|
| Quit | 485 | 137.789 | A | |
| Never | 244 | 137.72 | A | |
| Every Day | 107 | 131.17 | | B |
| Occasionally | 22 | 128.09 | A | B |

Means that do not share a letter are significantly different.

Tukey Simultaneous Tests for Differences of Means

| Difference of Levels | Difference of Means | SE of Difference | 95% CI | T-Value | Adjusted P-Value |
|--------------------------|---------------------|------------------|----------------|---------|------------------|
| Never - Every Day | 6.56 | 2.48 | (0.19; 12.92) | 2.64 | 0.041 |
| Occasionally - Every Day | -3.08 | 5.01 | (-15.93; 9.78) | -0.61 | 0.928 |
| Quit - Every Day | 6.62 | 2.28 | (0.76; 12.49) | 2.90 | 0.020 |
| Occasionally - Never | -9.63 | 4.76 | (-21.86; 2.59) | -2.02 | 0.179 |
| Quit - Never | 0.06 | 1.68 | (-4.25; 4.37) | 0.04 | 1.000 |
| Quit - Occasionally | 9.70 | 4.66 | (-2.27; 21.67) | 2.08 | 0.160 |

Individual confidence level = 98.96%

Analysis of variance shows since the p value from the one-way ANOVA ($p=0.006$) is much smaller than 0.005, shows the strong evidence to reject the null hypothesis.

As we can conclude some difference among the Sysbp, it is required to identify that which Smoking status impacts are significantly different for risk score of CHD. This is achieved by using a multiple comparisons procedure for the difference in population mean of Sysbp between each pair of Smoking.Status.

Tukey comparison, shows that the group which quit the smoking shows the decreases in risk profile comparing to the everyday group and same is for Quit and everyday group as the p value is less than .05 and confidence interval contains the positive value.

Secondary Endpoint Analysis:

Our considered secondary endpoint for this study Previous.MI and Hypertension and Diabetes and according to the previous conducted research, these endpoint shows the relevant difference in negative directions in case of risk scoring of CHD among adult males and females which is the very most reason to include these in our study.

Table 7: - Odd ratio of FRS scores among adults.

| Risk Factor | Odds Ratio for CHD | 95% CI | P value |
|--------------------|---------------------------|---------------|----------------|
| Hypertension | 4.84 | 4.23 – 5.53 | <0.001 |
| Obesity | 2.98 | 2.60 – 3.41 | <0.001 |
| Diabetes | 4.20 | 3.60 – 4.90 | <0.001 |

1: Previous.Mi

We carried out analysis first pie chart comparison between control and treatment which is followed by a formal analysis which took place as 2 proportion tests. To carry out the analysis research, the missing data is removed, and test is performed on filtered data for more accuracy in result.

Before carrying out the 2 proportion, tally cross tabulation chi square was conducted to evaluate the individual percentage.

Note: For pie chart and table for cross tabulation result please, follow the appendix.

Table- 8:

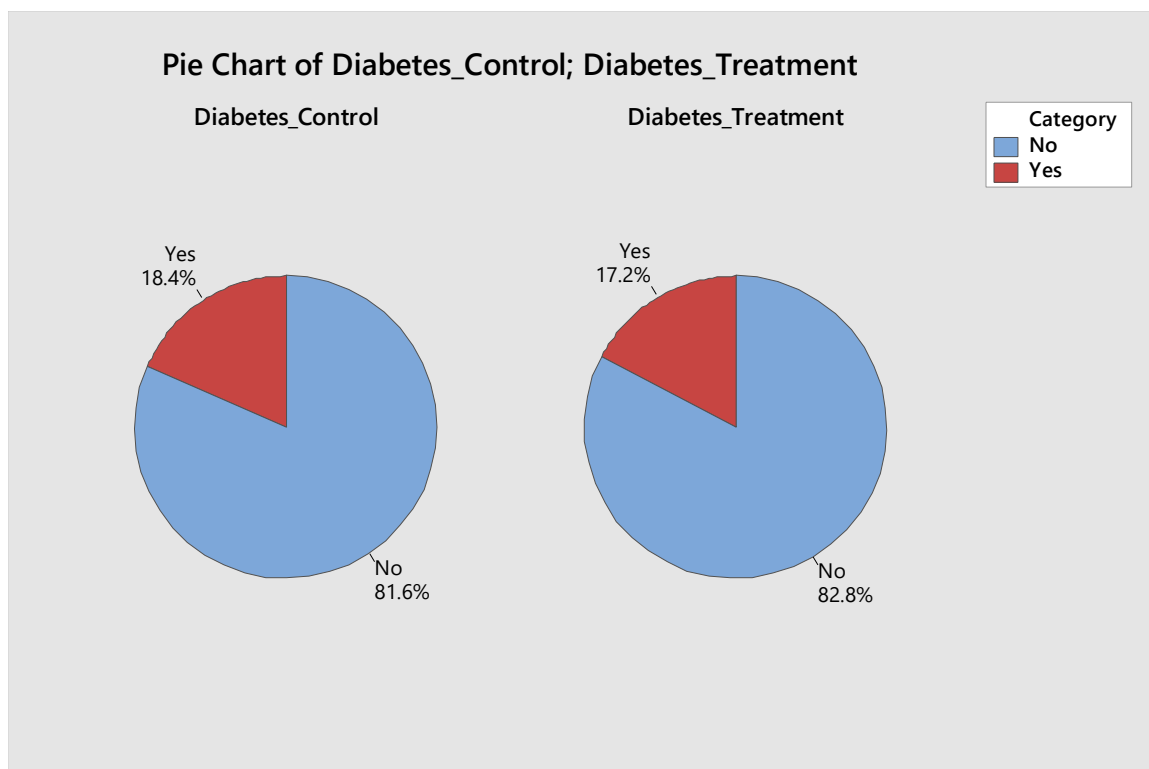

| Test and CI for Two Proportions: Control & Treatment | | | |
|---|--|---------|----------|
| Method | | | |
| Event: Previous.MI_Control = Yes | | | |
| p ₁ : proportion where Previous.MI_Control = Yes and Previous.MI_Treatment = No | | | |
| p ₂ : proportion where Previous.MI_Control = Yes and Previous.MI_Treatment = Yes | | | |
| Difference: p ₁ - p ₂ | | | |
| Descriptive Statistics: Previous.MI_Control | | | |
| Previous.MI_Treatment | N | Event | Sample p |
| No | 215 | 106 | 0.493023 |
| Yes | 214 | 109 | 0.509346 |
| Estimation for Difference | | | |
| | 95% CI for | | |
| Difference | Difference | | |
| <hr/> | | | |
| -0.0163225 (-0.110938; 0.078293) | | | |
| CI based on normal approximation | | | |
| Test | | | |
| Null hypothesis | H ₀ : p ₁ - p ₂ = 0 | | |
| Alternative hypothesis | H ₁ : p ₁ - p ₂ ≠ 0 | | |
| Method | Z-Value | P-Value | |
| <hr/> | | | |
| Normal approximation | -0.34 | 0.735 | |
| Fisher's exact | | 0.772 | |

The 2 proportion result the weak evidence to reject the null hypothesis due to our 95% confidence interval between 7% to 11% and does contain Zero and our $p > .05$. Hence it indicates that there is not significant difference between the previous history of control and treatment.

2: Hypertension and Diabetes

Analysis was carried out on Hypertension and Diabetes. Subjective analysis of Pie chart and cross Chi square tabulation which was followed by a formal analysis of 2 proportion for both second baseline endpoint.

Figure: Pie Chart of control and treatment for Diabetes and Hypertension.

Note: Kindly follow appendix for the descriptive analysis.

| CI based on normal approximation | | | |
| Test | | | |
| Null hypothesis | H ₀ : p ₁ - p ₂ = 0 | | |
| Alternative hypothesis | H ₁ : p ₁ - p ₂ ≠ 0 | | |
| Method | Z-Value | P-Value | |
| Normal approximation | 0.93 | 0.354 | |
| Fisher's exact | | 0.509 | |

Formal analysis for Hypertension and diabetes between control and treatment group has weak evidence against evidence null hypothesis due to fisher exact p value which is much bigger than .05 and 95% confidence intervals does contain zero. So, our analysis proves that Hypertension and Diabetes does not impact significantly the risk profile between the control and treatment. Primary and secondary analysis shows the difference respective the baseline

point which should be closely examine while interpretation of results to ensure the accuracy of result for expected and fair results.**Result**

There was a statistically significant positive correlation between Avgscores and core parameters (age, gender) and the severity of CHD according to the $p < 0.05$. Also, there was no statistically significant difference between Hypertension, Diabetes and Previous. MI according to $p > 0.05$ in Control and Treatment arm. On the other hand, there was no statistically significant difference between Avgscore of Control and Treatment as the $p > 0.05$. Wherein paired t shows that there is significant difference between the Male and Female population of Control and Treatment Arm and female population has less risk score comparing to men's according to 95% CI and p value. Smoking was also an important factor in the difference between both groups as the population who quit and who smoke Every day has significant.

Conclusion

There is no significant between the treatment and control population among risk score however the Female of control group has 13% to 16% less change gets the CHD comparing to men wherein in treatment Females has 14 % to 19% less change to get the CHD comparing to men. Risk scores increases as the age increase in males of control and treatment group, including this population is quit or never smoking has less chances of developing the CHD.

APPENDIX A

DATA Manipulation Using R

Datasets used for the study were analysed using the R language. And while analysing it was observed that it contains the missing value for several fields.

Following are the steps which has been performed to filter the data before any statistical analysis.

Selection of column for analysis.

Replace NA with mean value for Continuous columns

Removing NA for categorical Column

Calculate Risk Score adding cholesterol, Sysbp and Subtract HDL.

Round Off them score to zero decimal

Now Filter AvgScore by Male and Female.

Refer to below mentioned code

```
#installing required package.  
  
install.packages("dplyr")  
  
library(dplyr)  
  
#Reading the dataset  
  
a<-read.csv("Sphere.csv")  
  
#Printing summary to know mikssing data
```

```

summary(a)

#Selecting the desired data set to work on

a <-a %>%

  select(Arm,Gender, Smoking.Status, Previous.MI, Cholesterol, HDL, SysBP,
         Diabetes, Hypertension)

# Removing Missing value for cetegorical data

a<-a[!is.na(a$Smoking.Status), ]

a<-a[!is.na(a$Diabetes), ]

summary(a)

# Replacing na with mean for continous data

A$Cholesterol[which(is.na(A$Cholesterol))<- mean(A$Cholesterol, na.rm = TRUE)

A$HDL[which(is.na(A$HDL))<- mean(A$HDL, na.rm = TRUE)

A$SysBP[which(is.na(A$SysBP))<- mean(A$SysBP, na.rm = TRUE)

#Box Plot to know the outlier for the continous data

boxplot(A$Cholesterol)

boxplot(A$HDL)

boxplot(A$SysBP)

```

#Calculating the Avgscore from continuous data.

a\$Average<-a\$SysBP + a\$Cholesterol - a\$HDL

print(a)

Filtered data for Analysis.

| Arm | Gender | Smoking.Status | Previous.MI | Cholesterol | HDL | SysBP | AvgScore | Diabetes | Hypertension |
|-----------|--------|----------------|-------------|-------------|------|-------|----------|----------|--------------|
| Treatment | Female | Quit | No | 2.9 | 1.27 | 80 | 82 | No | Yes |
| Control | Male | Never | Yes | 4 | 1.27 | 80 | 83 | Yes | Yes |

APPENDIX B

This appendix is used to support the statistical analysis which was performed on the sphere data to investigate the difference between two arms control and treatment.

Figure 1: Pie chart of Control and Treatment for Previous.MI

Table 1:

Tabulated Statistics: Previous.MI_Control; Previous.MI_Treatment
Rows: Previous.MI_Control Columns: Previous.MI_Treatment

| | No | Yes | All |
|-----|--------------|--------------|---------------|
| No | 109 50.93 | 105 49.07 | 214 100.00 |
| Yes | 106 49.30 | 109 50.70 | 215 100.00 |
| All | 215 | 214 | 429 |

50.12 49.88 100.00

One-way ANOVA: Cholesterol versus Smoking.Status Method

Null hypothesis All means are equal
 Alternative hypothesis Not all means are equal
 Significance level $\alpha = 0.05$

Equal variances were assumed for the analysis.

Factor Information

| Factor | Levels | Values |
|----------------|--------|--------------------------------------|
| Smoking.Status | 4 | Every Day; Never; Occasionally; Quit |

Analysis of Variance

| Source | DF | Adj SS | Adj MS | F-Value | P-Value |
|----------------|-----|---------|--------|---------|---------|
| Smoking.Status | 3 | 3.644 | 1.2147 | 1.50 | 0.212 |
| Error | 854 | 689.370 | 0.8072 | | |
| Total | 857 | 693.014 | | | |

Model Summary

| S | R-sq | R-sq(adj) | R-sq(pred) |
|----------|-------|-----------|------------|
| 0.898457 | 0.53% | 0.18% | 0.00% |

Means

| Smoking.Status | N | Mean | StDev | 95% CI |
|----------------|-----|--------|--------|------------------|
| Every Day | 107 | 4.5233 | 0.8396 | (4.3528; 4.6937) |
| Never | 244 | 4.3611 | 0.9125 | (4.2483; 4.4740) |
| Occasionally | 22 | 4.565 | 0.980 | (4.189; 4.941) |
| Quit | 485 | 4.3443 | 0.9001 | (4.2642; 4.4243) |

Pooled StDev = 0.898457

Tukey Pairwise Comparisons

Grouping Information Using the Tukey Method and 95% Confidence

| Smoking.Status | N | Mean | Grouping |
|----------------|-----|--------|----------|
| Occasionally | 22 | 4.565 | A |
| Every Day | 107 | 4.5233 | A |
| Never | 244 | 4.3611 | A |
| Quit | 485 | 4.3443 | A |

Means that do not share a letter are significantly different.

Tukey Simultaneous Tests for Differences of Means

| Difference of Levels | Difference of Means | SE of Difference | 95% CI | T-Value | Adjusted P-Value |
|--------------------------|---------------------|------------------|-------------------|---------|------------------|
| Never - Every Day | -0.162 | 0.104 | (-0.430; 0.105) | -1.56 | 0.404 |
| Occasionally - Every Day | 0.041 | 0.210 | (-0.499; 0.581) | 0.20 | 0.997 |
| Quit - Every Day | -0.1790 | 0.0960 | (-0.4253; 0.0673) | -1.87 | 0.243 |

| | | | | | |
|----------------------|---------|--------|-------------------|-------|-------|
| Occasionally - Never | 0.203 | 0.200 | (-0.310; 0.717) | 1.02 | 0.740 |
| Quit - Never | -0.0169 | 0.0705 | (-0.1979; 0.1641) | -0.24 | 0.995 |
| Quit - Occasionally | -0.220 | 0.196 | (-0.723; 0.282) | -1.12 | 0.674 |

Individual confidence level = 98.96%
